We thank Drs Thomas R Hill and Ilias Kyriazakis for their comments on our paper. We agree that a clean label approach for food vitamin D enrichment is favoured by the consumer and the low levels of vitamin D<sub>3</sub> and 25(OH) D<sub>3</sub> naturally present in animal derived foods, such as eggs and milk, can be significantly increased by supplemental additions of vitamin D<sub>3</sub> and 25(OH) D<sub>3</sub> to the animals' diets (biofortification) (1). However, although a statistically significant increase in vitamin D<sub>3</sub> and 25(OH) D<sub>3</sub> has been reported after biofortification at supplemental quantities in line with EU legislation (2), these changes are quantitatively trivial and would not contribute to increase in dietary vitamin D<sub>3</sub> intake and human vitamin D status as stated by Drs Hill and Kryiazakis (1). We confirmed this in a recent study (3) in which dairy cows' diets were supplemented either with 0.075mg/kg vitamin D<sub>3</sub> (control), the maximum permitted dose of vitamin D<sub>3</sub> (0.1mg/kg) recommended by the EU (2), or with 0.03mg/kg vitamin D<sub>3</sub> plus 25(OH) D<sub>3</sub> (0.075 mg/kg) for 8 weeks feeding from calving to early lactation. The vitamin D<sub>3</sub> and 25(OH) D<sub>3</sub> concentrations in milk from both treatments were not significantly different to the control milk or to themselves (3). For a typical milk serving of 200 ml would contribute 0.02 to 0.66 µg vitamin D (3), which well below the current UK vitamin D recommended intake of 10 µg/day (4). The authors believe that without changes to the permitted dietary supplementation levels in dairy diets, milk fortification with vitamin D, may be a more feasible strategy to increase dietary vitamin D<sub>3</sub> intake and ultimately increase population vitamin D status, than biofortification.

Our current finding that a dairy drink fortified with 25(OH) D<sub>3</sub> was more effective at raising plasma 25(OH) D<sub>3</sub> concentrations than dairy drink fortified with vitamin D<sub>3</sub> in men with suboptimal vitamin D status supported previous studies (5, 6), which demonstrates the value of 25(OH) D<sub>3</sub> food fortification. However this would require changes in the EU legislation before the potential advantage of this form of vitamin D can be realised for food fortification in the EU.
